CARBAMIC ACID ESTER OF SUBSTITUTED 7-HYDROXY-2,3,4,5-TETRAHYDRO-1H-3-BENZAZEPINES

This invention relates to novel carbamic acid esters of substituted 7-hydroxy-2,3,4,5-tetrahydro-1H-3-benzazepines which are useful prodrugs for treatment of mental disorders. As used in this specification the term "prodrug" is defined as a derivative of a biologically active compound, which derivative, when absorbed into the blood stream of animals and humans, decomposes in such manner as to release the active substance and permits the latter to attain a higher bioavailability than that which would be obtained if the active substance, per se, was administered perorally. Thus, the active substance can be administered without problems intravenously; however, peroral administration is usually preferred for obvious reasons. Peroral administration of the active substance is often unsatisfactory, as it is decomposed in the gastrointestinal tract and during the first pass through the liver; but peroral administration of the prodrug has both the advantage of an easy administration and a high bioavailability.

Applicant's European patent application No. 86303001 describes 2,3,4,5-tetrahydro-1H-3-benzazepines useful in the treatment of mental disorders. If administered intravenously, these benzazepines are very useful in the treatment of mental disorders, as described in the European patent application; however, if administered orally they suffer from the disadvantage that very large doses have to be given in order to obtain the wanted effect.

Thus, a need exists for a measure, by means of which the benzazepines described in European patent application No. 86303001 can be administered orally in much smaller doses and yet generate the wanted effect.

Now, according to the invention it has been found that a selected category of the benzazepines described in European patent application No. 86303001, i.e. the category carrying a (phenolic) hydroxy group at the position No. 7 in the benzazepine nucleus (corresponding to the case of R³ being hydroxy in the terminology of the European patent application) can be converted to useful prodrugs, if certain selected carbamic acid esters are formed of the members belonging to this selected category of benzazepines.

Thus, the carbamic acid esters of substituted 7-hydroxy-2,3,4,5-tetrahydro-1H-3-benzazepines according to the invention have the general formula I

10 preferably the acid halide

whereafter (I) is isolated and if wanted converted to a salt.

25 As appears from the above, several active centers can be present in the carbamic acid esters according to the invention. It is to be understood that the invention comprises both racemates and all optical isomers.

The new compounds may be synthesized by esterification of the 7-hydroxy-benzazepine with an active carbamic acid derivative. In order to synthesize the new compounds also various new intermediates have been synthesized according to methods published in the literature. Thus, carbamoyl chlorides of N-substituted amino pro-moieties are prepared by reacting the actual N-substituted amino compound in its base form with phosgene in a suitable organic solvent (vide e.g. J.Org.Chem., 51, 1986, 3494-3498), and isocyanates of unsubstituted amino pro-moieties are generally prepared by reacting the amino compound in its base form with the diphosgene reagent trichloromethyl chloroformate (TCF, e.g. J.Org.Chem. 41, 1976, 2070-71; Org.Synth., 59, 1979, 195-201). The identity of these pro-moiety intermediates are confirmed by microanalysis, IR, and ¹H NMR spectroscopy.

35 In European patent application No. 170 090 it is stated in the paragraph bridging pages 4 and 5 that there is no way to accurately predict which prodrug structure will be suitable for a particular drug, and that a derivative which will work well for one drug may not do so for another, as differences in absorption, metabolism, distribution, and excretion among drugs do not permit generalizations to be made about prodrug design. Also, from page 34 in this European patent application No. 170 090 it appears that different (but related) parent substances with the same prodrug moiety exhibit widely varying relative bioavailabilities, which confirms the above finding that there is no way to accurately predict which prodrug structure will be suitable for a particular drug, even if a similar drug is known to exhibit a satisfactory relative bioavailability with a specific prodrug structure.

45 Thus, even if it appears from US patent No. 4,284,555 that a certain class of benzazepines can be esterified with carbamic acid esters to form prodrugs with improved relative bioavailability, the parent substances in this invention (the previously described subgroup of the benzazepines described in European patent application No. 86303001) differ significantly from the benzazepines described in US patent No. 4,284,555, and thus there would be no accurate way to predict which kind of prodrug structure would be suitable for the parent substances in the invention.

50 The prodrug effect is measured as the ratio between the area under the curve representing the concentration of the parent substance in the blood stream versus time in case of oral administration of the prodrug and the corresponding area in case of intravenous administration of an equimolar amount of the corresponding parent compound. In the sense of this invention the parent compound corresponding to a certain prodrug is a compound related to the prodrug, the only difference being that the position No. 7 in the parent compound carries the unesterified phenolic hydroxy group only. It has been found that mainly the parent compound is found in the blood stream if the prodrug is administered orally.

For more detailed information in regard to prodrug definition reference can be made to A.A. Sinkula and

S.H. Yalkowsky; J.Pharm.Sci., 64, 1975, 183-210, H. Bundgaard (ed.) (1985), Design of Prodrugs, Elsevier, Amsterdam, E.B. Roche (ed.) 1977, Design of Biopharmaceutical Properties through Prodrugs and Analogs, American Pharmaceutical Association, Washington D.C.

More precisely, the prodrug effect of the bioavailability is measured in the following manner.

5 The prodrug is administered perorally to a test animal and in a total dose designated "dose_{p.o.}". The concentration of the parent substance in the blood in mg of parent substance/ml of plasma is measured at regular time intervals after administration, and a curve representing this concentration versus time, e.g. in hours, is drawn up. The area under the curve (AUC_{p.o.}) in (mg/ml) x minutes is calculated.

Similarly the parent substance is administered intravenously in a total dose designated "dose_{i.v.}". A
10 similar curve is drawn up, and the area below this curve is similarly "AUC_{i.v.}".

Now, the bioavailability F is calculated according to the formula

$$15 \quad F = \frac{AUC_{p.o.}/dose_{p.o.}}{AUC_{i.v.}/dose_{i.v.}} \cdot 100\%$$

20 More specifically, in relation to this invention the bioavailability of the prodrugs is measured in dogs.

In a cross-over study parent substance and corresponding prodrug are administered with an interval of one week, the parent substance as an intravenous bolus and the corresponding prodrug as an oral solution, respectively.

By means of solid phase extraction of the plasma samples and HPLC the plasma concentration of both
25 parent substance and prodrug is estimated up to 24 hours after administration.

After the examples illustrating the synthesis of the prodrugs findings in regard to the bioavailability of some of the exemplified prodrugs and some prodrugs chemically related thereto will be presented.

The invention will be further illustrated by the following examples.
